Audience and Purpose

This report is intended for people who are interested in looking at SPDK Vhost scsi and blk stack performance and comparison to its Linux kernel equivalents. It provides performance and efficiency comparisons between SPDK Vhost-scsi and Linux Kernel Vhost-scsi software stacks under various test cases.

The purpose of this report is not to imply a single correct approach, but rather to provide a baseline of well-tested configurations and procedures that produce repeatable and reproducible results. This report can also be viewed as information regarding best known method when performance testing SPDK Vhost-scsi and Vhost-blk stacks.

Linux kernel version	5.9.16-200.fc33.x86_64
Additional boot options in /etc/default/grub	Multi queue enabled: scsi_mod.use_blk_mq=1

Introduction to the SPDK Vhost target

SPDK Vhost is a userspace target designed to extend the performance efficiencies of SPDK into QEMU/KVM virtualization environments. The SPDK Vhost-scsi target presents a broad range of SPDK-managed block devices into virtual machines. SPDK community has leveraged existing SPDK SCSI layer, DPDK Vhost library, QEMU Vhost-scsi and Vhost-blk functionality to create the high performance SPDK userspace Vhost target.

SPDK Vhost target architecture

QEMU sets up the Vhost target via UNIX domain socket. QEMU pre-allocates huge pages for the guest VM to enable DMA by the Vhost target. The guest VM submits I/O directly to the Vhost target via virtqueues in shared memory as shown in Figure 1. The Vhost target transfers data to/from the guest VM via shared memory. The Vhost target then completes I/O to the guest VM via virtqueues in shared memory. There is a completion interrupt sent using eventfd which requires a system call and a guest VM exit. It should be noted that there is no QEMU intervention during the I/O submission process.

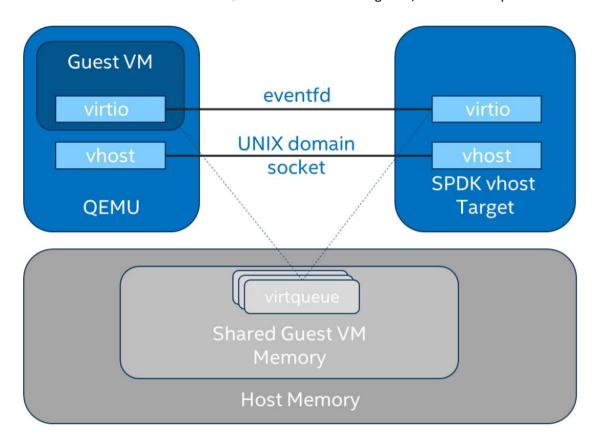

Figure 1: SPDK Vhost-scsi architecture

This report shows the performance comparisons between the traditional interrupt-driven Linux Kernel Vhost-scsi and the accelerated polled-mode SPDK Vhost-scsi under 3 different test cases using local

SPDK Vhost Performance Report Release 22.01

NVMe storage. Additionally, the SPDK Vhost-blk stack is included in the report for further comparison with the SCSI stack.

Test Case 1: SPDK Vhost Core Scaling

This test case was performed in order to understand aggregate VM performance with SPDK Vhost I/O core scaling. We ran up to 36 virtual machines, each running following FIO workloads:

- 4KB 100% Random Read
- 4KB 100% Random Write
- 4KB Random 70% Read / 30 % Write

We increased the number of CPU cores used by SPDK Vhost target to process I/O from 1 up to 12 and measured the throughput (in IOPS) and latency. The number of VMs between test runs was not constant and was increased by 6 for each Vhost CPU added, up to a maximum of 36 VMs. VM number was not increased beyond 36 because of the platform capabilities in terms of available CPU cores.

FIO was run in client-server mode. FIO client was run on the host machine and distributed jobs to FIO servers run on each VM. This allowed us to start the FIO jobs across all VMs at the same time.

Results in the table and charts represent aggregate performance (IOPS and average latency) seen across all the VMs. The results are average of 3 runs.

Table 4: SPDK Vhost Core Scaling test configuration

Table 4. SFDR VIIOSEC	ore Scaling test configuration		
Item	Description		
Test case	Test SPDK Vhost target I/O core scaling performance		
Test configuration	FIO Version: fio-3.19		
	VM Configuration:		
	 Common settings are described in the <u>Virtual Machine Settings</u> chapter. 		
	 Number of VMs: variable (6 VMs per 1 Vhost CPU core, up to 36 VMs max). Each VM has a single Vhost device as a target for the FIO workload. This is achieved by sharing SPDK NVMe bdevs by using either a Split NVMe vbdev or Logical Volume bdev configuration. 		
	 SPDK Vhost target configuration: Test were run with both the Vhost-scsi and Vhost-blk stacks. The Vhost-scsi stack was run with Split NVMe bdevs and Logical Volume bdevs. Vhost-blk stack was run with Logical Volume bdevs. Tests were performed with 1, 2, 4, 6, 8, 10 and 12 Vhost cores for each stack-bdey combination. 		
	Kernel Vhost target configuration: - N/A		
FIO configuration	[global] ioengine=libaio

Logical Volumes performance impact

The SPDK Vhost SCSI tests were run using two bdev backends – Split NVMes and Logical Volumes. Both "Split NVMe Bdevs" and "Logical Volume Bdevs" allow to logically partition NVMe SSDs, the latter being more flexible in configuration. Here we measure the overhead of extra flexibility afforded by Logical Volumes.

Table 8: Logical Volumes performance impact for SPDK Vhost SCSI

Workload	# of CPU cores	# of VMs	Vhost SCSI + Split NVMe IOPS (millions)	Vhost SCSI + Lvol IOPS (millions)	Lvol Impact (%)

write	10	36	5.79	5.85	1.00%
	12	36	5.91	6.13	3.64%

Packed Ring performance impact

Selected test cases were re-run to show benefits of using Packed Rings as an option when configuring SPDK Vhost BLK controllers. For this, an optional parameter "—packed_ring" must be used when creating a SPDK Vhost BLK controller. Packed Ring feature requires QEMU 4.2.0 or later.

Table 9: Packed Ring performance impact on SPDK Vhost BLK controllers.

Workload	# of CPU cores	# of VMs	IOPS (millions) Split Ring	IOPS (millions) Packed Ring	Avg. Latency (usec) Split Ring	Avg. Latency (usec) Packed Ring	Packed Ring IOPS impact (%)	Packed Ring Avg. Latency impact (%)

Conclusions

- 1. For SPDK Vhost SCSI performance with split NVMe bdevs, we measured 1.70 million IOPS on one Vhost core for the 4KB 100% Random Write workload. The single Vhost core IOPS for 4 KB Random Read and 4KB Random 70/30 Read/Write were 1.90 million and 1.74 million IOPS respectively. For all workloads, the IOPS scaled near linearly with addition of I/O processing cores up to 6 CPU cores. Peak performance was achieved at 8 CPU cores for all workloads. Further increasing the number of cores does not result in performance improvement or it is not significant.
- 2. For SPDK Vhost SCSI with Logical Volume backend devices, we measured about 1.5 million IOPS on one Vhost core for all 3 workloads. Performance scaled near linearly with addition of I/O processing cores up to 8 CPU cores for Random Read and up to 6 CPU cores for other workloads. Increasing the number of I/O processing cores further results in non-linear IOPS gains. Peak performance is reached at 12 CPU cores for Random Read and Random Read/Write workloads and at 8 CPU cores for Random Write workload.
- 3. For SPDK Vhost BLK with Logical Volume backend devices, we measured about 1.6 million IOPS on one Vhost core for all workloads. Performance scaled near linearly up to 8 CPU cores for Random Read and up to 6 CPU cores for other workloads. Increasing the number of cores improves performance further, but the gains are not linear.
- 4. Using Logical Volumes has an impact of 5-17% lower IOPS when Vhost saturates the I/O cores at 6 or less CPUs. Further increasing SPDK Vhost CPU cores allow Logical Volumes to perform better and their performance is on par with Split NVMe Bdevs (less than 10% difference).
- 5. For some workloads there is a slight performance drop when Vhost is run with 10 or 12 CPU cores. The platform has 80 CPU threads available, and 36 VMs use 72 CPU threads. Therefore, when 10 or 12 are used for the Vhost process there is not enough left to accommodate all the VMs. Some of the VMs share CPU threads, thus becoming less efficient.
- 6. Using Packed Ring option instead of default Split Ring mode for SPDK Vhost BLK controllers results in minor performance improvement.
- 7. Using vfio-user along with vfio-user-pci devices attached to Qemu guest VMs results in 20-60% lower performance than using SPDK vhost-user-scsi-pci. Delta between SPDK vhost SCSI and SPDK vfio-user decreases with addition of CPU cores to target process.
- 8. For 4k Random Read and 4k Random Write workload SPDK vfio-user performance trend is rising with addition of CPU cores to target process. This suggests that IOPS throughput at some point might reach the same values as for SPDK Vhost stack. However, we were unable to verify this, as there were no free CPU cores left in the system. Increasing the number of CPU cores for Target would have to be done at expense of number of running Qemu guest VMs, which would lower the overall performance.

15

Test Case 2: Rate Limiting IOPS per VM

This test case was geared towards understanding how many VMs can be supported at a pre-defined Quality of Service of IOPS per Vhost device. Both read and write IOPS were rate limited for each Vhost device on each of the VMs and then VM density was compared between SPDK & the Linux Kernel. 10K IOPS per VM were chosen as the rate limiter using Linux cgroups2.

Each individual VM was running FIO with the following workloads:

- 4KB 100% Random Read
- 4KB 100% Random Write

The results in tables are average of 3 runs.

Table 10: Rate Limiting	I IOPS per VM test case configuration
Item	Description
Item	Description
Test case	Test rate limiting IOPS/VM to 10000 IOPS
Test configuration	FIO Version: fio-3.19
	VM Configuration:
	Common settings are described in the <u>Virtual Machine Settings</u> chapter.
	 Number of VMs: 24, 48, and 72 Each VM has a single Vhost device which is one of equal partitions of NVMe drive. Total number of partitions depends on run test case. For 24 VMs: 24xNVMe * 1 partition per NVMe = 24 partitions For 48 VMs: 24xNVMe * 2 partitions per NVMe = 48 partitions For 72 VMs: 24xNVMe * 3 partitions per NVMe = 72 partitions Devices on VMs were throttled to run at a maximum of 10k IOPS (read or write)
	SPDK Vhost target configuration:
	Test were run with both Vhost-scsi and Vhost-blk stacks.
	 The Vhost-scsi stack was run with Split NVMe bdevs and Logical Volume bdevs.
	The Vhost-blk stack was run with Logical Volume bdevs.
	Test were run with the Vhost target using 4 CPU cores (NUMA optimized).
	Kernel Vhost-scsi configuration:
	 Cgroups were used to limit the Vhost process to 4 cores.
	NUMA optimizations were not explored.

Figure 6: 4KB 100% Random Writes IOPS, QD=1, throttling = 10k IOPS

Conclusions

- 1. Using just 4 I/O processing cores, the SPDK vhost served 10,000 IOPS/VM to up to 48 VMs for 4 KB random read workload and 72 VMs for the 4 KB random write workload.
- 2. The Kernel Vhost was not able to serve IO at 10K IOPS/VM with just 4 I/O processing cores for the 4KB random read workload. For the 4K Rand write the Kernel Vhost target served 10K IOPS/VM to up to 24 VMs
- 3. Average latencies were up to 2.3x times better for Random Read and up to 2.1x times better for Random Write workloads with the SPDK Vhost when compared to Kernel Vhost.

Test Case 3: Performance per NVMe drive

This test case was performed in order to understand performance and efficiency of the Vhost scsi and blk process using SPDK vs. Linux Kernel with a single NVMe drive on 2 VMs. Each VM had a single Vhost device which is one of two equal partitions of an NVMe drive. Results in the table represent performance (IOPS, avg. latency & CPU %) seen from the VM. The VM was running FIO with the following workloads:

- 4KB 100% Random Read
- 4KB 100% Random Write
- 4KB Random 70% Read 30% Write

The results in tables are average of 3 runs.

	 Common settings are described in the <u>Virtual Machine Settings</u> chapter. 2 VMs were tested Each VM had a single Vhost device which was one of two equal partitions of a single NVMe drive.
	 SPDK Vhost target configuration: The SPDK Vhost process was run on a single, physical CPU core. The Vhost-scsi stack was run with Split NVMe bdevs and Logical Volume bdevs. The Vhost-blk stack was run with Logical Volume bdevs. Kernel Vhost target configuration: The Vhost process was run on a single, physical CPU core using cgroups.
FIO configuration	[global] ioengine=libaio direct=1 rw=randrw rwmixread=100 (100% reads), 70 (70% reads, 30% writes), 0 (100% writes) thread=1 norandommap=1 time_based=1 runtime=240s ramp_time=60s bs=4k iodepth=1 / 8 / 32 / 64 numjobs=1

Conclusions

1. SPDK Vhost-scsi with NVMe Split bdevs has lower latency and higher throughput than Kernel Vhost-scsi in majority of workload / queue depth combinations.

This report compared performance results while running Vhost-scsi using traditional interrupt-driven kernel Vhost-scsi against the accelerated polled-mode driven SPDK implementation. Various local ephemeral configurations were demonstrated, including rate limiting IOPS, performance per VM, and maximum performance from an underlying system when comparing kernel vs. SPDK Vhost-scsi target implementations.

In addition, performance impacts of using SPDK Logical Volume Bdevs and the SPDK Vhost-blk stack were presented.

This report provided information regarding methodologies and practices while benchmarking Vhost-scsi and Vhost-blk using both SPDK and the Linux Kernel. It should be noted that the performance data showcased in this report is based on specific hardware and software configurations and that performance results may vary depending on different hardware and software configurations.

Appendix A - Vfio-User Performance

Vfio-user is a framework that allows implementing PCI devices in userspace. Clients, such as Qemu, talk to the server over a UNIX socket using vfio-user protocol. For more information see: libvfio-user.

SPDK has added a vfio-user transport to the nvmf target. This allows presenting a virtual NVMe PCIe device to a client, such as a Qemu VM. This is analogous to how the SPDK vhost target presents virtual virtio PCIe devices to a Qemu VM.

The performance comparison between SPDK Vhost stacks versus vfio-user transport layer was done using <u>oracle/qemu fork</u> (vfio-user-v0.93 branch), which supports running Qemu guest VMs with "vfio-user-pci" devices.

In SPDK v22.01, the vfio-user transport triggers an interrupt (vfio_irq_trigger) for every NVMe completion – it has no ability to coalesce interrupts. This is the primary reason why the vfio-user results collected for v22.01 are significantly lower than vhost-blk. The vhost-blk target is able to coalesce interrupts, resulting in much higher performance. Eliminating unnecessary interrupts reduces interrupt overhead in the guest VM, but also reduces system call overhead in the SPDK target application. The SPDK v22.05 release will use the NVMe queue pair's cq_head to identify opportunities to coalesce interrupts – preliminary testing shows that the performance puts NVMe vfio-user on par with vhost-blk.
